Background: Radiotherapy (RT) is recommended to all patients undergoing Breast Conserving Surgery (BCS). Two strategies can be applied to irradiation, External Beam RT (EBRT) in addition, Intraoperative Radiation Therapy (IORT). The aim of this study was to introduce a protein biomarker panel related to molecular function of IORT. **Materials and Methods:** Six Breast Cancer (BC) patients as a pilot study were treated by 12 Gy (Boost dose) and 21 Gy (Radical dose). Samples tissue included Margin before IORT (MB), and Margin 24 hours After IORT (MA24 h). High-throughput technology such as Isobaric Tag for Relative and Absolute Quantitation (iTRAQ) was performed to study proteomic of IORT-treated tumor bed. **Results:** We classified 110 differentially expressed proteins (DEPs) as a protein biomarker panel by mapping the annotated coding region sequences to the reference canonical pathways in the KEGG database. **Conclusion:** The analyses of protein function and signaling pathways of these DEPs reveal a molecular response to the effectiveness of IORT.

Keywords: Intraoperative radiation therapy (IORT), proteomic.

INTRODUCTION

BC as the fifth leading cause of cancer death is recognized as the most common cancer among women ⁽¹⁾. Considering the advances in early diagnosis and treatment of BC, mortality has reduced by 38% from 1989 to 2014 ⁽²⁾. The prevalence of BC was 9795 cases in Iran, and the age-adjusted standardized ratio (ASR) was 28.1 in 100 000 people ⁽³⁾. Akbari *et al.* reported that the five- and ten-year survival rate for BC was estimated to be 81% and 77%, respectively ⁽⁴⁾.

RT is recommended to all patients undergoing BCS and some of them after

mastectomy. The main objective is to obtain more effective doses of radiation in the appropriate time and site without increasing the prevalence of complications. RT can provide curative treatment in nearly 40% of patients ⁽⁵⁾. In a previous study, long-term outcomes in patients with BCS and RT who were timely diagnosed, were similar to or even better than patients with mastectomy ⁽⁶⁾.

Two strategies can be applied to deliver irradiation to the cancer site. The first strategy is the use EBRT which is delivered from outside the body to the tumor site via protons, photons, or charged particles ⁽⁷⁾. The second strategy is

IORT which delivers electron beams (IOeRT) and low kV-X-ray (IOXRT) ⁽⁸⁾.

By applying IORT during BCS, a high single dose is delivered to the site at the highest risk to fight subclinical tumor cell contamination with high precision owing to direct visualization ⁽⁹⁾. Tumor bed has been reported as the highest risk of breast tumor recurrence ^(10,11). As a result, local recurrence can be significantly reduced by using an extra dose to the tumor bed ⁽¹²⁾.

EBRT can be replaced by accelerating partial breast irradiation, including an IORT session, due to approved several advantages including; lack of gap between surgery and RT, avoidance of long treatment duration, reduced radiation-induced toxicity, tumor bed delineation under direct palpation and visual assessments and sparing non-targeted tissues surrounding the tumor bed ^(12,13). In addition to the delayed time of RT after tumor excision, EBRT has harmful effects, including cardiac attack, appearance of second tumors, or stimulation of tumor cell growth by neo angiogenesis and hypoxia condition ⁽¹⁴⁾. Notably, IORT can also help to save money, time, and CO₂ emissions in some patients, inhibiting transportation ⁽¹⁵⁾.

According to specific eligibility criteria, IORT may be delivered either as an anticipated Boost, followed by conventional external RT to guarantee optimal dose delivery, or as an exclusive single radiation dose of Radical, corresponding to the administration of the entire sequence of conventional adjuvant RT ^(16,17).

Some studies have demonstrated that the biological effects of RT vary depending on the dose and irradiation time. In this regard, study on MCF7 cells treated with 9 and 23 Gy was suggested dose-dependent gene-expression profiles that might regulate cell-fate decision in two different ways. The high-dose treatments inhibited the growth and proliferation of MCF7 cells and the post-irradiation cell traits showed a typical senescent phenotype, confirmed by senescence-SA-β-Gal activity, which increased in a dose and time-dependent manner ⁽¹⁸⁾. Another study on IORT-treated tumor bed suggested that functional annotation and gene ontology (GO)

indicated that significant enrichment in molecular pathways on BC treatment is somehow single high dose-independent ⁽¹⁹⁾.

The aim of this study was to introduce a protein biomarker panel (as a pilot study) related to molecular functions of IORT-treated tumor bed. The overall goal of this project is to identify molecules related to therapeutic techniques such as IORT that can discover some of the complexities of these processes for future aspects of personalized RT.

MATERIALS AND METHODS

Six random selected BC patients (as a pilot study) entered into our study (table 1). These eligible patients had neither comorbidity / history of drug nor significant mental health disorder. Informed Consent from patients and Institutional Ethical Approval from Shahid Beheshti University of Medical Sciences was obtained with approval ID: IR.SBMU.RETECH.REC.1397.561 and approval date: 2018-05-13.

IORT delivered electron beams (LIAC linear accelerators, Sordina IOeRT Technologies S.p.A, Italy), and an Intraoperative accelerator was employed for cell irradiation ⁽²⁰⁾. Patients were treated with irradiation following two separate strategies, including Boost and Radical dose treatment. The machine dose rate was adjusted to 1 cGy/MU during the irradiation.

Approximately 100 mg of margin tissue was extracted before IORT (MB) as a normal group. Likewise, at the time of operation while the wound is open, in direct vision, irradiated tumor margin (under Boost and Radical) marked. Small piece of margin tissue with narrow pedicle sutured to thread and the end of thread exited from the wound, the skin incision closed except 5-10 mm left to open for final (24 hours after operation) sample extraction. The sample removed without any pain or disturbance and dressing applied. This sample named MA24 h under Boost and Radical doses.

Protein extraction

First total proteins were extracted from

samples with the TRIzol reagent used as supplied by Invitrogen Life Technologies. Then

proteins of more than 200µg qualified also were labeled to be used for iTRAQ.

Table 1. Clinical and pathological data of six BC patients under IORT-treated tumor bed.

Proteomics assays

Peptide labeling

Peptide labeling was performed by iTRAQ Reagent 8-plex Kit according to the manufacturer's protocol. The labeled peptides with different reagents were combined and desalted.

Peptide 1st dimensional fractionation

The peptides were reconstituted with buffer A (5% ACN, 95% H₂O, adjusted pH to 9.8 with ammonia) and separated by a Shimadzu LC-20AB HPLC system coupled with a high pH RP column (5-µm particles, Phenomenex). The peptides were separated at a flow rate of 1 ml/min with a 60 min gradient: 5% buffer B (5% H₂O, 95% ACN, adjusted pH to 9.8 with ammonia) for 10 min, 5-35% buffer B for 40min, 35-95% buffer B for 1 min, and 95% buffer B for 3 min. The gradient was then decreased to 5% B within 1 min before re-equilibrating with 5% buffer B for 5 min. Elution was monitored by measuring absorbance at 214 nm and the eluted peptides were pooled as 20 fractions in a concatenation mode and vacuum dried.

Peptide 2nd dimensional fractionation

Each fraction was re-suspended in buffer A (2% ACN and 0.1% FA in water) and loaded onto

a C18 trap column using an LC-20AD nano-HPLC instrument (Shimadzu, Kyoto, Japan) by the Autosampler. Then, the peptides were eluted from the trap column and separated by an analytical C18 column (inner diameter 75 µm × 20 cm, 3µm) packed in-house. The gradient was run at 300 nL/min starting from 8 to 35% of buffer B (2% H₂O and 0.1% FA in ACN) for 35 minutes, increasing to 60% for 5 minutes, then maintaining at 80% B for 5 minutes, and finally returning to 5% in 0.1 min and keeping for 10 min.

Mass spectrometer detection

Data acquisition was performed with a TripleTOF 5600 System (SCIEX, Framingham, MA, USA) equipped with a Nanospray III source (SCIEX, Framingham, MA, USA), a pulled quartz tip as the emitter (New Objectives, Woburn, MA) and controlled with software Analyst 1.6 (AB SCIEX, Concord, ON). Data was acquired with the following MS conditions: ion spray voltage of 2,300 V, curtain gas of 30, nebulizer gas of 15, and interface heater temperature of 150 °C. High sensitivity mode was used for the whole data acquisition. The mass ranges for MS1 were from 350 to 1500 Da. Based on the intensity in MS1 survey, as many as 30 product ion scans were collected if exceeding a threshold of 120 counts

per second (counts/s) and with charge-state 2+ to 5+, dynamic exclusion was set for 1/2 of the peak width (12 s). For iTRAQ data acquisition, the collision energy was adjusted to all precursor ions for collision-induced dissociation and the Q2 transmission window for 100 Da was 100%.

Protein identification and quantification

The raw MS/MS data were converted into MGF format by ProteoWizard tool msConvert, and the exported MGF files were searched using Mascot version 2.3.02 (Matrix Science, London, UK). In this project against the human Uniprot database. To reduce the probability of false peptide identification, only those peptides with significant scores (≥ 20) with 99% confidence were counted as identified. The IQuant software was used to quantitatively analyze the labeled peptides with isobaric tags ⁽²¹⁾. It integrates Mascot Percolator, a well performing machine learning method for re-scoring database search results, to provide reliable significance measures. In order to assess the confidence of peptides, the PSMs were pre-filtered at a PSM-level FDR of 1%. Then, based on the "simple principle" (The parsimony principle), identified peptide sequences were assembled into a set of confident proteins. In order to control the rate of false-positive at the protein level, a protein FDR at 1%, which is based on Picked protein FDR strategy will also be estimated after protein inference (Protein-level FDR ≤ 0.01) ⁽²²⁾. The protein quantification process includes the following steps: Protein identification, Tag impurity correction, Data normalization, Missing value imputation, Protein ratio calculation, Statistical analysis, and Results presentation. Proteins with 1.2-fold change and Q-value less than 0.05 were determined as differentially expressed protein. For quantification repeat analysis, we used CV to evaluate the reproducibility. CV is defined as the ratio of the standard deviation (SD) to the mean.

Gene functional enrichment analysis

Gene functional enrichment analysis was applied on DEPs. In this study, we used

KEGG pathway database by using DAVID (<http://david.abcc.ncifcrf.gov/>) for functional enrichment analysis.

Network analysis of DEPs

Cytoscape network analysis represented the most important proteins based on degree ⁽¹⁹⁾.

RESULTS

Identification of differentially expressed proteins classification

We performed iTRAQ quantification after labeling of samples in three replicates (Boost / Radical, and MB/ MA24 h). In total, 1045410 spectrums were generated; also, 31572 peptides and 5860 proteins were identified with 1% FDR. DEPs for each comparisons of group/treatments analyzed. We found that there were 110 DEPs (37 up regulated, 73 down regulated) as single high dose-independent, which were common in both Boost and Radical doses (table 2).

Table 2. Represented common DEPs in both Boost and Radical doses.

Names	total	elements

Network Analysis of DEPs as single high dose-independent

We have analyzed 110 DEPs as single high dose-independent. Cytoscape network analysis represented the most important proteins based on 110 nodes, 350 edges and 6.36 as average node degree and 0.505 as avg. local clustering coefficient (figure 1).

Figure 1. Network analysis of 110 DEPs as single high dose-independent based on degree by string database.

According to figure 2, we identified a network of 110 DEPs as single high dose-independent. Among all, we found key proteins as a protein biomarker panel under Boost and Radical doses.

Figure 2. The deregulated densest protein-protein network (blue nodes: proteins, red nodes: proteins involved in crucial pathways) in 110 DEPs as single high dose-independent (Boost and Radical).

Gene ontology enrichment and functional classification 24 h post irradiation

For the better understanding of the molecular factions of IORT, we classified 110 DEPs by mapping the annotated coding region sequences to the reference canonical pathways in the KEGG pathway database (figure 3).

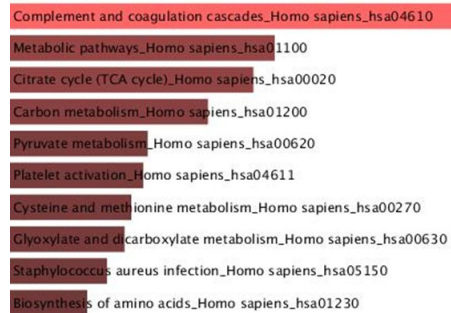

Figure 3. Biological pathways on 110 DEPs under 24 h after Boost and Radical doses by KEGG database.

DISCUSSION

RT is recommended to all patients undergoing BCS and some of them after mastectomy⁽²³⁾. Despite the technological advances made in recent decades, RT plans still advise the same total dose per organ tumor, without taking into account the biological differences attributable to the different tumor subtypes⁽²⁴⁾. By applying IORT during BCS, a high single dose is delivered to the site at the highest risk to fight subclinical tumor cell contamination with high precision owing to direct visualization⁽⁹⁾. Tumor bed has been reported as the highest risk of breast tumor recurrence^(10,11). As a result, local recurrence can be significantly reduced by using an extra dose to the tumor bed⁽¹²⁾.

Although researchers have shown great interest in a single high-dose clinical approaches for different cancers, limited research has examined the biological and molecular basis of single high-dose effects, especially after IORT⁽²⁵⁾. In the context of this radiation treatment modality, this study aimed to describe the molecular response, in terms of DEPs and pathways, according to the different doses of

IORT. However, this type of investigation would need to be extended to numerous panels of samples; thus, the present work should be considered as a pilot study. Here, we report substantial alterations in proteins expression levels 24 h after RT in both dose (Boost and Radical). In this study proteomics approach, using ITRAQ is a necessary first step for biological pathways to describe the common molecular features associated with types of IORT. As previously described, samples were divided into two groups according to their irradiation. Then DEPs and key pathways related to RT were compared.

In this comparison, we detected 110 overlap DEPs between Boost and Radical (table 2). The identified overlapping DEPs extracted from 24 h post-treatment are enriched based on KEGG pathways database by using DAVID. We have analyzed 110 DEPs as single high dose-independent. Cytoscape network analysis represented the most important proteins (figure 1). All DEPs were classified into 10 protein categories (figure 2), in which the most proteins related to RT are PLG, VWF and A2M (figure 2).

As previously described by several authors, radiation effects on cells are heterogeneous and appear to act in a cell line-dependent way. This behavior was also confirmed by the pathway analysis conducted ^(26, 27). A few studies have described that, in the MCF7 cell line, the 9 Gy IR-related cell cycle, DNA replication, DNA damage response, meiotic processes, cell cycle regulation, repairing DNA strand breaks and cell survival/death balance through the activation of apoptosis signaling were deregulated after irradiation.

The Plasminogen system produced by PLG (plasminogen) plays a crucial role in physiological in addition, pathological events related to tissue regeneration, wound healing, immune response, angiogenesis, invasion and metastasis. The PLG is significantly downregulated after IORT-treated tumor bed and highly enriched in Complement and coagulation cascades.

In addition, Von Willebrand Factor Protein

(VWF) is a major platelet ligand that has been widely used, as a biomarker in cancer growth and metastasis and associated inflammation, is significantly downregulated at 24 h post irradiation also highly enriched in complement and coagulation cascades. As shown in figure 4, refer to complement and coagulation cascades kegg pathway data base, enrichment associated with changes in these related key pathway to RT have been illustrated which indicates that two doses of IORT (figure 3) is able to reduce cell growth and cell proliferation.

Functional annotation revealed new insights of IORT in BC patients. Local pathways and systemic effects; such as Complement and coagulation cascades, phagosome, metabolomics pathways and immune responses were enriched through IORT (figure 3).

Eventually, results revealed new insights of IORT in BC management; all of these biological responses in tumor cells may be towards effectiveness of IORT and it shows that although IORT is a local treatment, it can have systemic effects.

CONCLUSION

IORT can support targeted and accurate treatment of patients by modulating the surrounding tissue around the tumor. We suggest a protein biomarker panel for efficacy of IORT. However, this type of investigation would need to be extended to numerous panels of samples; thus, the present work should be considered as a pilot study

By using comprehensive techniques such as proteomic, we found the molecular basis of IORT -related changes that have already showed clinical and epidemiological effects in treating BC patients. In addition, key molecular pathways that induced by IORT indicated that, cellular microenvironment as a main cause of changes in cells through tumor development, can be affected by IORT. Due to the effectiveness of IORT, it may be recommended as a standard method for BC patients.
